DIRECTED POLYMERS ON HIERARCHICAL LATTICES WITH SITE DISORDER.

HUBERT LACOIN AND GREGORIO MORENO

Abstract. We study a polymer model on hierarchical lattices very close to the one introduced and studied in [19, 16]. For this model, we prove the existence of free energy and derive the necessary and sufficient condition for which very strong disorder holds for all β, and give some accurate results on the behavior of the free energy at high-temperature. We obtain these results by using a combination of fractional moment method and change of measure over the environment to obtain an upper bound, and second moment method to get a lower bound. We also get lower bounds on the fluctuation exponent of $\log Z_n$, and study the infinite polymer measure in the weak disorder phase.

1. Introduction and presentation of the model

The model of directed polymers in random environment appeared first in the physics literature as an attempt to modelize roughening in domain wall in the $2D$-Ising model due to impurities [28]. It then reached the mathematical community in [29], and in [4], where the author applied martingale techniques that have became the major technical tools in the study of this model since then. A lot of progress has been made recently in the mathematical understanding of directed polymer model (see for example [30, 15, 11, 14, 7, 8, 13] and [12] for a recent review). It is known that there is a phase transition from a delocalized phase at high temperature, where the behavior of the polymer is diffusive, to a localized phase, where it is expected that the influence of the media is relevant in order to produce nontrivial phenomenons, such as super-diffusivity. These two different situations are usually referred to as weak and strong disorder, respectively. A simple characterization of this dichotomy is given in terms of the limit of a certain positive martingale related to the partition function of this model.

It is known that in low dimensions ($d = 1$ or 2), the polymer is essentially in the strong disorder phase (see [36], for more precise results), but for $d \geqslant 3$, there is a nontrivial region of temperatures where weak disorder holds. A weak form of invariance principle is proved in [15].

However, the exact value of the critical temperature which separates the two regions (when it is finite) remains an open question. It is known exactly in the case of directed polymers on the tree, where a complete analysis is available (see [5, 22, 32]). In the case of $\mathbb{Z}^d$, for $d \geqslant 3$, an L^2 computation yields an upper bound on the critical temperature, which is however known not to coincide with this bound (see [3, 2] and [6]).

We choose to study the same model of directed polymers on diamond hierarchical lattices. These lattices present a very simple structure allowing to perform a lot of computations together with a richer geometry than the tree (see Remark 2.3 for more details). They have been introduced in physics in order to perform exact renormalization group computations for spin systems ([38, 31]). A detailed treatment of more general hierarchical lattices can be found in [33] and [34]. For an overview of the extensive literature on Ising and Potts models on hierarchical lattices, we refer the reader to [1, 17] and references therein. Whereas statistical mechanics model on trees have to be considered as mean-field versions of the original models, the hierarchical lattice models are in many sense very close to the models on $\mathbb{Z}^d$; they are a very powerful tool to get an intuition for results and proofs on the more complex $\mathbb{Z}^d$ models (for instance, the work on hierarchical pinning model in [23] lead to a solution of the original model in [21]. In the same manner, the present work has been a great source of inspiration for [36]).

Directed polymers on hierarchical lattices (with bond disorder) appeared in [16, 18, 19, 20] (see also [39] for directed first-passage percolation). More recently, these lattice models raised the interest of mathematicians in the study of random resistor networks ([40]), pinning/wetting transitions ([23, 35]) and diffusion on a percolation cluster ([27]).

We can also mention [26] where the authors consider a random analogue of the hierarchical lattice, where at each step, each bond transforms either into a series of two bonds or into two bonds in parallel, with probability p and $p-1$ respectively.

Our aim in this paper is to describe the properties of the quenched free energy of directed polymers on hierarchical lattices with site disorder at high temperature:

- First, to be able to decide, in all cases, if the quenched and annealed free energy differ at low temperature.
- If they do, we want to be able to describe the phase transition and to compute the critical exponent.

We choose to focus on the model with site disorder, whereas [25, 16] focus on the model with *bond disorder* where computations are simpler. We do so because we believe that this model is closer to the model of directed polymer in $\mathbb{Z}^d$ (in particular, because of the inhomogeneity of the Green Function), and because there exists a nice recursive construction of the partition functions in our case, that leads to a martingale property. Apart from that, both models are very similar, and we will shortly talk about the bound disorder model in section 8.

The diamond hierarchical lattice D_n can be constructed recursively:

- D_0 is one single edge linking two vertices A and B.
- D_{n+1} is obtained from D_n by replacing each edges by b branches of $s-1$ edges.

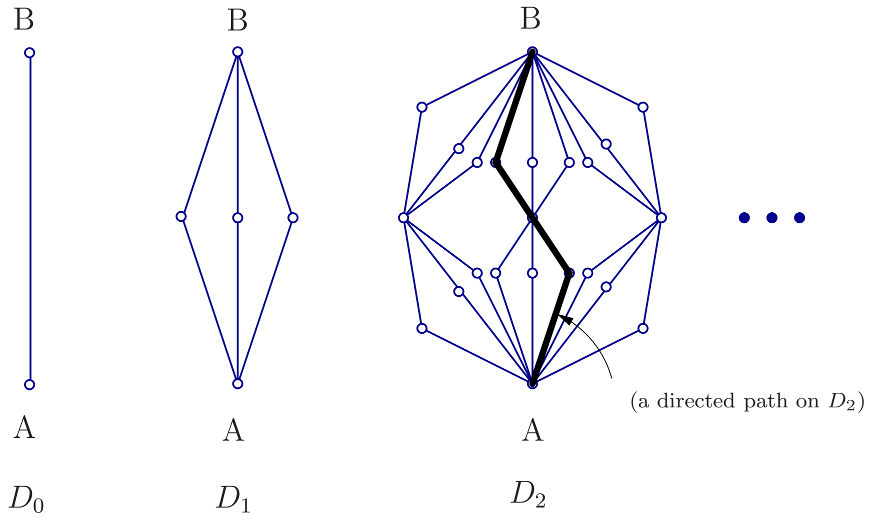

FIGURE 1. We present here the recursive construction of the first three levels of the hierarchical lattice D_n, for $b=3$, $s=2$.

We can, improperly, consider D_n as a set of vertices, and, with the above construction, we have $D_n \subset D_{n+1}$. We set $D = \bigcup_{n \geqslant 0} D_n$. The vertices introduced at the n-th iteration are said to belong to the n-th generation $V_n = D_n \setminus D_{n-1}$. We easily see that $|V_n| = (bs)^{n-1}b(s-1)$.
We restrict to $b \geqslant 2$ and $s \geqslant 2$. The case $b = 1$ (resp. $s = 1$) is not interesting as it just corresponds to a familly of edges in serie (resp. in parallel)

We introduce disorder in the system as a set of real numbers associated to vertices $\omega = (\omega_z)_{z \in D \setminus \{A,B\}}$. Consider Γ_n the space of directed paths in D_n linking A to B. For each $g \in \Gamma_n$ (to be understood as a sequence of connected vertices in D_n, $(g_0 = A, g_1, \ldots, g_{s^n} = B)$), we define the Hamiltonian

$$H_n^\omega(g) := \sum_{t=1}^{s^n-1} \omega(g_t). \tag{1.1}$$

For $\beta > 0$, $n \geqslant 1$, we define the (quenched) polymer measure on Γ_n which chooses a path γ at random with law

$$\mu_{\beta,n}^\omega(\gamma = g) := \frac{1}{Z_n(\beta)} \exp(\beta H_n^\omega(g)), \tag{1.2}$$

where

$$Z_n(\beta) = Z_n(\beta, \omega) := \sum_{g \in \Gamma_n} \exp(\beta H_n^\omega(g)), \tag{1.3}$$

is the partition function, and β is the inverse temperature parameter.

In the sequel, we will focus on the case where $\omega = (\omega_z,\ z \in D \setminus \{A,B\})$ is a collection of i.i.d. random variables and denote the product measure by Q. Let ω_0 denote a one dimensional marginal of Q, we assume that ω_0 has expectation zero, unit variance, and that

$$\lambda(\beta) := \log Q e^{\beta\omega_0} < \infty \quad \forall \beta > 0. \tag{1.4}$$

As usual, we define the quenched free energy (see Theorem 2.1) by

$$p(\beta) := \lim_{n \to +\infty} \frac{1}{s^n} Q \log Z_n(\beta), \tag{1.5}$$

and its annealed counterpart by

$$f(\beta) := \lim_{n \to +\infty} \frac{1}{s^n} \log Q Z_n(\beta). \tag{1.6}$$

This annealed free energy can be exactly computed. We will prove

$$f(\beta) := \lambda(\beta) + \frac{\log b}{s-1}. \tag{1.7}$$

This model can also be stated as a random dynamical system: given two integer parameters b and s larger than 2, $\beta > 0$, consider the following recursion:

$$\begin{aligned} W_0 &\overset{\mathcal{L}}{=} 1 \\ W_{n+1} &\overset{\mathcal{L}}{=} \frac{1}{b} \sum_{i=1}^{b} \prod_{j=1}^{s} W_n^{(i,j)} \prod_{i=1}^{s-1} A_n^{(i,j)}, \end{aligned} \tag{1.8}$$

where equalities hold in distribution, $W_n^{(i,j)}$ are independent copies of W_n, and $A_n^{(i,j)}$ are i.i.d. random variables, independent of the $W_n^{(i,j)}$ with law

$$A \overset{\mathcal{L}}{=} \exp(\beta\omega - \lambda(\beta)).$$

In the directed polymer setting, W_n can be interpretative as the normalized partition function

$$W_n(\beta) = W_n(\beta, \omega) = \frac{Z_n(\beta, \omega)}{QZ_n(\beta, \omega)}. \tag{1.9}$$

Then, (1.8) turns out to be an almost sure equality if we interpret $W_n^{(i,j)}$ as the partition function of the j-th edge of the i-th branch of D_1.
The sequence $(W_n)_{n\geqslant 0}$ is a martingale with respect to $\mathcal{F}_n = \sigma(\omega_z : z \in \cup_{i=1}^n V_i)$ and as $W_n > 0$ for all n, we can define the almost sure limit $W_\infty = \lim_{n\to+\infty} W_n$. Taking limits in both sides of (1.8), we obtain a functional equation for W_∞.

2. Results

Our first result is about the existence of the free energy.

Theorem 2.1. *For all β, the limit*

$$\lim_{n\to+\infty} \frac{1}{s^n} \log Z_n(\beta), \tag{2.1}$$

exists a.s. and is a.s. equal to the quenched free energy $p(\beta)$. In fact for any $\varepsilon > 0$, one can find $n_0(\varepsilon, \beta)$ such that

$$Q\left(|Z_n - Q\log Z_n| > s^n\varepsilon\right) \leqslant \exp\left(-\frac{\varepsilon^{2/3} s^{n/3}}{4}\right), \quad \text{for all } n \geqslant n_0 \tag{2.2}$$

Moreover, $p(\cdot)$ is a strictly convex function of β.

Remark 2.2. The inequality (2.2) is the exact equivalent of [11, Proposition 2.5], and the proof given there can easily be adapted to our case. It applies concentration results for martingales from [37]. It can be improved in order to obtain the same bound as for Gaussian environments stated in [8] (see [9] for details). However, it is believed that it is not of the optimal order, similar to the case of directed polymers on $\mathbb{Z}^d$.

Remark 2.3. The strict convexity of the free energy is an interesting property. It is known that it holds also for the directed polymer on $\mathbb{Z}^d$ but not on the tree. In the later case, the free energy is strictly convex only for values of β smaller than the critical value β_c (to be defined latter) and it is linear on $[\beta_c, +\infty)$. This fact is related to the particular structure of the tree that leads to major simplifications in the 'correlation' structure of the model (see [5]). The strict convexity, in our setting, arises essentially from the property that two path on the hierarchical lattice can re-interesect after being separated at some step. This underlines once more, that $\mathbb{Z}^d$ and the hierarchical lattice have a lot of features in common, which they do not share with the tree.

We next establish the martingale property for W_n and the zero-one law for its limit.

Lemma 2.4. *$(W_n)_n$ is a positive $\mathcal{F}_n$-martingale. It converges Q-almost surely to a non-negative limit W_∞ that satisfies the following zero-one law:*

$$Q\left(W_\infty > 0\right) \in \{0, 1\}. \tag{2.3}$$

Recall that martingales appear when the disorder is displayed on sites, in contrast with disorder on bonds as in [16, 18].

Observe that

$$p(\beta) - f(\beta) = \lim_{n\to+\infty} \frac{1}{s^n} \log W_n(\beta),$$

so, if we are in the situation $Q(W_\infty > 0) = 1$, we have that $p(\beta) = f(\beta)$. This motivates the following definition:

Definition 2.5. *If $Q(W_\infty > 0) = 1$, we say that weak disorder holds. In the opposite situation, we say that strong disorder holds.*

Remark 2.6. Later, we will give a statement(Proposition 5.1) that guarantees that strong disorder is equivalent to $p(\beta) \neq f(\beta)$, a situation that is sometimes called very strong disorder. This is believed to be true for polymer models on $\mathbb{Z}^d$ or $\mathbb{R}^d$ but it remains an unproved and challenging conjecture in dimension $d \geqslant 3$ (see [7]).

The next proposition lists a series of partial results that in some sense clarify the phase diagram of our model.

Proposition 2.7. *(i) There exists $\beta_0 \in [0, +\infty]$ such that strong disorder holds for $\beta > \beta_0$ and weak disorder holds for $\beta \leqslant \beta_0$.*

(ii) If $b > s$, $\beta_0 > 0$. Indeed, there exists $\beta_2 \in (0, \infty]$ such that for all $\beta < \beta_2$, $\sup_n Q(W_n^2(\beta)) < +\infty$, and therefore weak disorder holds.

(iii) If $\beta\lambda'(\beta)-\lambda(\beta)>\frac{2\log b}{s-1}$*, then strong disorder holds.*

(iv) In the case where ω_z *are gaussian random variables, (iii) can be improved for* $b>s$*: strong disorder holds as soon as* $\beta>\sqrt{\frac{2(b-s)\log b}{(b-1)(s-1)}}$.

(v) If $b\leqslant s$*, then strong disorder holds for all* β.

Remark 2.8. On can check that the formula in (*iii*) ensures that $\beta_0<\infty$ whenever the distribution of ω_z is unbounded.

Remark 2.9. An implicit formula is given for β_2 in the proof and this gives a lower bound for β_0. However, when $\beta_2<\infty$, it never coincides with the upper bound given by (*iii*) and (*iv*), and therefore knowing the exact value of the critical temperature when $b>s$ remains an open problem.

We now provide more quantitative information for the regime considered in (*v*):

Theorem 2.10. *When* $s>b$*, there exists a constant* $c_{s,b}=c$ *such that for any* $\beta\leqslant 1$ *we have*

$$\frac{1}{c}\beta^{\frac{2}{\alpha}}\leqslant\lambda(\beta)-p(\beta)\leqslant c\beta^{\frac{2}{\alpha}}$$

where $\alpha=\frac{\log s-\log b}{\log s}$.

Theorem 2.11. *When* $s=b$*, there exists a constant* $c_s=c$ *such that for any* $\beta\leqslant 1$ *we have*

$$\exp\left(-\frac{c}{\beta^2}\right)\leqslant\lambda(\beta)-p(\beta)\leqslant c\exp\left(-\frac{1}{c\beta}\right)$$

In the theory of directed polymer in random environment, it is believed that, in low dimension, the quantity $\log Z_n$ undergoes large fluctuations around its average (as opposed to what happens in the weak disorder regime where the fluctuation are of order 1). More precisely: it is believed that there exists exponents $\xi>0$ and $\chi\geqslant 0$ such that

$$\log Z_n-Q\log Z_n\asymp N^{\xi}\text{ and }\operatorname{Var}_Q\log Z_n\asymp N^{2\chi},\tag{2.4}$$

where N is the length of the system ($=n$ on $\mathbb{Z}^d$ and s^n one our hierarchical lattice). In the non-hierarchical model this exponent is of major importance as it is closely related to the *volume exponent* ξ that gives the spatial fluctuation of the polymer chain (see e.g. [30] for a discussion on fluctuation exponents). Indeed it is conjectured for the $\mathbb{Z}^d$ models that

$$\chi=2\xi-1.\tag{2.5}$$

This implies that the polymer trajectories are superdiffusive as soon as $\chi>0$. In our hierarchical setup, there is no such geometric interpretation but having a lower bound on the fluctuation allows to get a significant localization result.

Proposition 2.12. *When $b < s$, there exists a constant c such that for all $n \geqslant 0$ we have*

$$\mathrm{Var}_Q\left(\log Z_n\right) \geqslant \frac{c(s/b)^n}{\beta^2}. \tag{2.6}$$

Moreover, for any $\varepsilon > 0$, $n \geqslant 0$, and $a \in \mathbb{R}$,

$$Q\left\{\log Z_n \in [a, a+\varepsilon(s/b)^{n/2}]\right\} \leqslant \frac{8\varepsilon}{\beta}. \tag{2.7}$$

This implies that if the fluctuation exponent χ exists, $\chi \geqslant \frac{\log s - \log b}{2\log s}$. We also have the corresponding result for the case $b = s$

Proposition 2.13. *When $b = s$, there exists a constant c such that for all $n \geqslant 0$ we have*

$$\mathrm{Var}_Q\left(\log Z_n\right) \geqslant \frac{cn}{\beta^2}. \tag{2.8}$$

Moreover for any $\varepsilon > 0$, $n \geqslant 0$, and $a \in \mathbb{R}$,

$$Q\left\{\log Z_n \in [a, a+\varepsilon\sqrt{n}]\right\} \leqslant \frac{8\varepsilon}{\beta}. \tag{2.9}$$

From the fluctuations of the free energy we can prove the following: For $g \in \Gamma_n$ and $m < n$, we define $g|_m$ to be the restriction of g to D_m.

Corollary 2.14. *If $b \leqslant s$, and n is fixed we have*

$$\lim_{n\to\infty} \sup_{g\in\Gamma_m} \mu_n(\gamma|_m = g) = 1, \tag{2.10}$$

where the convergence holds in probability.

Intuitively this result means that if one look on a large scale, the law of μ_n is concentrated in the neighborhood of a single path. Equipping Γ_n with a natural metric (two path g and g' in Γ_n are at distance 2^{-m} if and only if $g|_m \neq g'|_m$ and $g|_{m-1} = g|_{m-1}$) makes this statement rigorous.

Remark 2.15. Proposition 2.7(v) brings the idea that $b \leqslant s$ for this hierarchical model is equivalent to the $d \leqslant 2$ case for the model in $\mathbb{Z}^d$ (and that $b > s$ is equivalent to $d > 2$). Let us push further the analogy: let $\gamma^{(1)}$, $\gamma^{(2)}$ be two paths chosen uniformly at random in Γ_n (denote the uniform-product law by $P^{\otimes 2}$), their expected site overlap is of order $(s/b)^n$ if $b < s$, of order n if $b = s$, and of order 1 if $b > s$. If one denotes by $N = s^n$ the length of the system, one has

$$P^{\otimes 2}\left[\sum_{t=0}^{N} \mathbf{1}_{\{\gamma_t^{(1)}=\gamma_t^{(2)}\}}\right] \asymp \begin{cases} N^\alpha \quad \text{if } b < s, \\ \log N \quad \text{if } b = s, \\ 1 \text{ if } b > s, \end{cases} \tag{2.11}$$

(where $\alpha = (\log s - \log b)/\log s$). Comparing this to the case of random walk on $\mathbb{Z}^d$, we can infer that the case $b = s$ is just like $d = 2$ and that the case $d = 1$ is similar to $b = \sqrt{s}$ ($\alpha = 1/2$). One can check in comparing [36, Theorem 1.4, 1.5, 1.6] with Theorem 2.10 and 2.11, that this analogy is relevant.

The paper is organised as follow

- In section 3 we prove some basic statements about the free energy, Lemma 2.4 and the first part of Proposition 2.7.
- Item (*ii*) from Proposition 2.7 is proved in Section 5.1. Item (*v*) is a consequence of Theorems 2.10 and 2.11.
- Items (*iii*) and (*iv*) are proved in Section 6.3. Theorems 2.10 and 2.11 are proved in Section 6.1 and 6.3 respectively.
- In section 6 we prove Propositions 2.12 and 2.13 and Corrolary 2.14.
- In section 7 we define and investigate the properties of the infinite volume polymer measure in the weak disorder phase.
- In section 8 we shortly discuss about the bond disorder model.

3. Martingale tricks and free energy

We first look at to the existence of the quenched free energy

$$p(\beta)=\lim_{n\to+\infty}\frac{1}{n}Q\left(\log Z_n(\beta)\right),$$

and its relation with the annealed free energy. The case $\beta=0$ is somehow instructive. It gives the number of paths in Γ_n and is handled by the simple recursion:

$$Z_n(0)=b\left(Z_{n-1}(0)\right).$$

This easily yields

$$|\Gamma_n|=Z_n(\beta=0)=b^{\frac{s^n-1}{s-1}}. \tag{3.1}$$

Much in the same spirit than (1.8), we can find a recursion for Z_n:

$$Z_{n+1}=\sum_{i=1}^{b}Z_n^{(i,1)}\cdots Z_n^{(i,s)}\times e^{\beta\omega_{i,1}}\cdots e^{\beta\omega_{i,s-1}}. \tag{3.2}$$

The existence of the quenched free energy follows by monotonicity: we have

$$Z_{n+1}\geqslant Z_n^{(1,1)}Z_n^{(1,2)}\cdots Z_n^{(1,s)}\times e^{\beta\omega_{1,1}}\cdots e^{\beta\omega_{1,s-1}},$$

so that (recall the ω's are centered random variables)

$$\frac{1}{s^{n+1}}Q\log Z_{n+1}\geqslant\frac{1}{s^n}Q\log Z_n.$$

The annealed free energy provides an upper bound:

$$\begin{aligned}\frac{1}{s^n} Q \log Z_n &\leqslant \frac{1}{s^n} \log Q Z_n \\ &= \frac{1}{s^n} \log e^{\lambda(\beta)(s^n-1)} Z_n(\beta=0) \\ &= \left(1-\frac{1}{s^n}\right)\left(\lambda(\beta)+\frac{\log b}{s-1}\right) \\ &= \left(1-\frac{1}{s^n}\right) f(\beta).\end{aligned}$$

We now prove the strict convexity of the free energy. The proof is essentially borrowed from [10], but it is remarkably simpler in our case.

Proof of the strict convexity of the free energy. We will consider a Bernoulli environment ($\omega_z = \pm 1$ with probability p, $1-p$; note that our assumptions on the variance and expectation for ω are violated but centering and rescaling ω does not change the argument). We refer to [10] for generalization to more general environment.

An easy computation yields

$$\frac{d^2}{d\beta^2} Q \log Z_n = Q \mathrm{Var}_{\mu_n} H_n(\gamma).$$

We will prove that for each $K > 0$, there exists a constant C such that, for all $\beta \in [0, K]$ and $n \geqslant 1$,

$$\mathrm{Var}_{\mu_n} H_n(\gamma) \geqslant C s^n \tag{3.3}$$

For $g \in \Gamma_n$ and $m < n$, we define $g|_m$ to be the restriction of g to D_m. By the conditional variance formula,

$$\begin{aligned}\mathrm{Var}_{\mu_n} H_n &= \mu_n\left(\mathrm{Var}_{\mu_n}(H_n(\gamma)\,|\,\gamma_{|n-1})\right) + \mathrm{Var}_{\mu_n}\left(\mu_n(H_n(\gamma)\,|\,\gamma_{|n-1})\right) \\ &\geqslant \mu_n\left(\mathrm{Var}_{\mu_n}(H_n(\gamma)\,|\,\gamma_{|n-1})\right)\end{aligned} \tag{3.4}$$

Now, for $l = 0, ..., s^{n-1}-1$, $g \in \Gamma_n$, define

$$H_n^{(l)}(g) = \sum_{t=ls+1}^{(l+1)s-1} \omega(g_t),$$

so (3.4) is equal to

$$\mu_n \mathrm{Var}_{\mu_n}\left(\sum_{l=0}^{s^{n-1}-1} H_n^{(l)}(\gamma)|\gamma_{|n-1}\right) = \sum_{l=0}^{s^{n-1}-1} \mu_n \mathrm{Var}_{\mu_n}\left(H_n^{(l)}(\gamma)|\gamma_{|n-1}\right),$$

by independence. Summarizing,

$$\mathrm{Var}_{\mu_n} H_n \geqslant \sum_{l=1}^{s^{n-1}} \mu_n \mathrm{Var}_{\mu_n}\left(H_n^{(l)}(\gamma)|\gamma_{|n-1}\right). \tag{3.5}$$

The rest of the proof consists in showing that each term of the sum is bounded from below by a positive constant, uniformly in l and n. For any $x \in D_{n-1}$ such that the graph distance between x and A is ls in D_n (i.e. $x \in D_{n-1}$), we define the set of environment

$$M(n,l,x) = \left\{\omega : \left|\{H_n^{(l)}(g,\omega)\ :\ g \in \Gamma_n, g_{ls} = x\}\right| \geqslant 2\right\}.$$

These environments provide the fluctuations in the energy needed for the uniform lower bound we are searching for. One second suffices to convince oneself that $Q(M(n,l,x) > 0$, and does not depend on the parameters n, l or x. Let $Q(M)$ denote improperly the common value of $Q(M(n,l,x))$. Now, it is easy to see (from (3.5)) that there exists a constant C such that for all $\beta < K$,

$$Q\left[\mathrm{Var}_{\mu_n} H_n\right] \quad \geqslant \quad CQ\left[\sum_{l=1}^{s^{n-1}-1} \sum_{x \in D_{n-1}} \mathbf{1}_{M(n,l,x)} \mu_n(\gamma_{ls} = x)\right].$$

Define now $\mu_n^{(l)}$ as the polymer measure in the environment obtained from ω by setting $\omega(y) = 0$ for all sites y which distance to 0 is between ls and $(l+1)s$. One can check that for all n, and all path g,

$$\exp(-2\beta(s-1))\mu_n^{(l)}(\gamma = g) \leqslant \mu_n(\gamma = g) \leqslant \exp(2\beta(s-1))\mu_n^{(l)}(\gamma).$$

We note that under Q, $\mu_n^{(l)}(\gamma_{ls} = x)$ and $\mathbf{1}_{M(n,l,x)}$ are random variables, so that

$$\begin{aligned} Q\left[\mathrm{Var}_{\mu_n} H_n\right] \quad &\geqslant \quad C\exp(-2\beta(s-1))Q\left[\sum_{l=0}^{s^{n-1}-1} \sum_{x} \mathbf{1}_{M(n,l,x)} \mu_n^{(l)}(\gamma_{ls} = x)\right] \\ &= \quad C\exp(-2\beta(s-1)) \sum_{l=1}^{s^{n-1}} \sum_{x \in D_{n-1}} Q(M(n,l,x)) Q\left[\mu_n^{(l)}(\gamma_l = x)\right] \\ &= \quad C\exp(-2\beta(s-1))Q(M)s^{n-1}. \end{aligned}$$

□

We now establish the martingale property for the normalized free energy.

Proof of Lemma 2.4. Set $z_n = Z_n(\beta = 0)$. We have already remarked that this is just the number of (directed) paths in D_n, and its value is given by (3.1). Observe that $g \in \Gamma_n$ visits $s^n(s-1)$ sites of $n+1$-th generation. The restriction of paths in

D_{n+1} to D_n is obviously not one-to-one as for each path $g' \in \Gamma_n$, there are b^{s^n} paths in Γ_{n+1} such that $g|_n = g'$. Now,

$$\begin{aligned}
Q\left(Z_{n+1}(\beta)|\mathcal{F}_n\right) &= \sum_{g\in D_{n+1}} Q\left(e^{\beta H_{n+1}(g)}|\mathcal{F}_n\right)\\
&= \sum_{g'\in D_n}\sum_{g\in D_{n+1}} Q\left(e^{\beta H_{n+1}(g)}|\mathcal{F}_n\right)\mathbf{1}_{g|_n=g'}\\
&= \sum_{g'\in D_n}\sum_{g\in D_{n+1}} e^{\beta H_n(g')}e^{s^n(s-1)\lambda(\beta)}\mathbf{1}_{g|_n=g'}\\
&= \sum_{g'\in D_n} e^{\beta H_n(g')}e^{s^n(s-1)\lambda(\beta)}\sum_{g\in D_{n+1}}\mathbf{1}_{g|_n=g'}\\
&= e^{s^n(s-1)\lambda(\beta)}b^{s^n}\sum_{g'\in D_n} e^{\beta H_n(g')}\\
&= Z_n(\beta)\frac{z_{n+1}e^{s^{n+1}\lambda(\beta)}}{z_n e^{s^n\lambda(\beta)}}.
\end{aligned}$$

This proves the martingale property. For (2.3), let's generalize a little the preceding restriction procedure. As before, for a path $g \in D_{n+k}$, denote by $g|_n$ its restriction to D_n. Denote by $I_{n,n+k}$ the set of time indexes that have been removed in order to perform this restriction and by $N_{n,n+k}$ its cardinality. Then

$$Z_{n+k} = \sum_{g\in D_n} e^{\beta H_n(g)} \sum_{g'\in D_{n+k}, g'|_n=g} \exp\left\{\beta \sum_{t\in I_{n,n+k}} \omega(g'_t)\right\}.$$

Consider the following notation, for $g \in \Gamma_n$,

$$\widetilde{W}_{n,n+k}(g) = c_{n,n+k}^{-1} \sum_{g'\in D_{n+k}, g'|_n=g} \exp\left\{\beta \sum_{t\in I_{n,n+k}} \omega(g'_t) - N_{n,n+k}\lambda(\beta)\right\},$$

where $c_{n,n+k}$ stands for the number paths in the sum. With this notations, we have,

$$W_{n+k} = \frac{1}{z_n}\sum_{g\in D_n} e^{\beta H_n(g)-(s^n-1)\lambda(\beta)}\widetilde{W}_{n,n+k}(g), \tag{3.6}$$

and, for all n,

$$\{W_\infty = 0\} = \left\{\widetilde{W}_{n,n+k}(g) \to 0, \text{ as}\, k \to +\infty, \forall\, g \in D_n\right\}. \tag{3.7}$$

The event in the right hand side is measurable with respect to the disorder of generation not earlier than n. As n is arbitrary, the right hand side of (3.7) is in the tail σ-algebra and its probability is either 0 or 1. □

This, combined with FKG-type arguments (see [15, Theorem 3.2] for details), proves part (*i*) of Proposition 2.7. Roughly speaking, the FKG inequality is used to insure that there is no reentrance phase.

4. Second moment method and lower bounds

This section contains all the proofs concerning coincidence of annealed and quenched free–energy for $s > b$ and lower bounds on the free–energy for $b \leqslant s$ (i.e. half of the results from Proposition 2.7 to Theorem 2.11.) First, we discuss briefly the condition on β that one has to fulfill to to have W_n bounded in $\mathbb{L}_2(Q)$. Then for the cases when strong disorder holds at all temperature ($b \leqslant s$), we present a method that combines control of the second moment up to some scale n and a percolation argument to get a lower bound on the free energy.
First we investigate how to get the variance of W_n (under Q). From (1.8) we get the induction for the variance $v_n = Q\left[(W_n - 1)^2\right]$:

$$\begin{aligned} v_{n+1} &= \frac{1}{b}\left(e^{(s-1)\gamma(\beta)}(v_n+1)^s - 1\right), \qquad (4.1)\\ v_0 &= 0. \qquad (4.2)\end{aligned}$$

where $\gamma(\beta) := \lambda(2\beta) - 2\lambda(\beta)$.

4.1. The L^2 domain: $s < b$.

If $b > s$, and $\gamma(\beta)$ is small, the map

$$g:\ x \mapsto \frac{1}{b}\left(e^{(s-1)\gamma(\beta)}(x+1)^s - 1\right)$$

possesses a fixed point. In this case, (4.1) guaranties that v_n converges to some finite limit. Therefore, in this case, W_n is a positive martingale bounded in $\mathbb{L}^2$, and therefore converges almost surely to $W_\infty \in \mathbb{L}^2(Q)$ with $QW_\infty = 1$, so that

$$p(\beta) - \lambda(\beta) = \lim_{n\to\infty} \frac{1}{s^n}\log W_n = 0,$$

and weak disorder holds. One can check that g has a fixed point if and only if

$$\gamma(\beta) \leqslant \frac{s}{s-1}\log\frac{s}{b} - \log\frac{b-1}{s-1}$$

4.2. Control of the variance: $s > b$.

For $\epsilon > 0$, let n_0 be the smallest integer such that $v_n \geqslant \varepsilon$.

Lemma 4.1. *For any $\varepsilon > 0$, there exists a constant c_ε such that for any $\beta \leqslant 1$*

$$n_0 \geqslant \frac{2|\log\beta|}{\log s - \log b} - c_\varepsilon.$$

Proof. Expanding (4.1) around $\beta = 0$, $v_n = 0$, we find a constant c_1 such that, whenever $v_n \leqslant 1$ and $\beta \leqslant 1$,

$$v_{n+1} \leqslant \frac{s}{b}(v_n + c_1\beta^2)(1 + c_1 v_n). \qquad (4.3)$$

Using (4.3), we obtain by induction

$$v_{n_0} \leqslant \prod_{i=0}^{n_0-1}(1+c_1 v_i)\left[c_1\beta^2\left(\sum_{i=0}^{n_0-1}(s/b)^i\right)\right].$$

From (4.1), we see that $v_{i+1} \geqslant (s/b)v_i$. By definition of n_0, $v_{n_0-1} < \epsilon$, so that $v_i < \varepsilon(s/b)^{i-n_0+1}$. Then

$$\prod_{i=0}^{n_0-1}(1+c_1 v_i) \leqslant \prod_{i=0}^{n_0-1}(1+c_1\varepsilon(s/b)^{i-n_0+1}) \leqslant \prod_{k=0}^{\infty}(1+c_1\varepsilon(s/b)^{-k}) \leqslant 2,$$

where the last inequality holds for ε small enough. In that case we have

$$\varepsilon \leqslant v_{n_0} \leqslant 2c_1\beta^2(s/b)^{n_0},$$

so that

$$n_0 \geqslant \frac{\log(\varepsilon/2c_1\beta^2)}{\log(s/b)}.$$

□

4.3. **Control of the variance:** $s = b$**.**

Lemma 4.2. *There exists a constant c_2 such that, for every $\beta \leqslant 1$,*

$$v_n \leqslant \beta, \quad \forall\, n \ \leqslant\ \frac{c_2}{\beta}.$$

Proof. By (4.3) and induction we have, for any n such that $v_{n-1} \leqslant 1$ and $\beta \leqslant 1$,

$$v_n \leqslant n\beta^2\prod_{i=0}^{n-1}(1+c_1 v_i).$$

Let n_0 be the smallest integer such that $v_{n_0} > \beta$. By the above formula, we have

$$v_{n_0} \leqslant n_0\beta^2(1+c_1\beta)^{n_0}$$

Suppose that $n_0 \leqslant (c_2/\beta)$, then

$$\beta \leqslant v_{n_0} \leqslant c_2 c_1\beta(1+c_1\beta)^{c_2/\beta}.$$

If c_4 is chosen small enough, this is impossible. □

4.4. **Directed percolation on** D_n**.** For technical reasons, we need to get some understanding on directed independent bond percolation on D_n. Let p be the probability that an edge is open (more detailed considerations about edge disorder are given in the last section). The probability of having an open path from A to B in D_n follows the recursion

$$\begin{aligned} p_0 &= p,\\ p_n &= 1-(1-p_{n-1}^s)^b. \end{aligned}$$

On can check that the map $x \mapsto 1-(1-x^s)^b$ has a unique unstable fixed point on $(0,1)$; we call it p_c. Therefore if $p > p_c$, with a probability tending to 1, there will be an open path linking A and B in D_n. If $p < p_c$, A and B will be disconnected in

D_n with probability tending to 1. If $p = p_c$, the probability that A and B are linked in D_n by an open path is stationary. See [27] for a deep investigation of percolation on hierarchical lattices.

4.5. **From control of the variance to lower bounds on the free energy.** Given b and s, let $p_c = p_c(b, s)$ be the critical parameter for directed bond percolation.

Proposition 4.3. *Let n be an integer such that $v_n = Q(W_n - 1)^2 < \frac{1-p_c}{4}$ and β such that $p(\beta) \leqslant (1 - \log 2)$. Then*

$$\lambda(\beta) - p(\beta) \geqslant s^{-n}$$

Proof. If n is such that $Q\left[(W_n - 1)^2\right] < \frac{1-p_c}{4}$, we apply Chebycheff inequality to see that

$$Q(W_n < 1/2) \leqslant 4v_n < 1 - p_c.$$

Now let be $m \geqslant n$. D_m can be seen as the graph D_{m-n} where the edges have been replaced by i.i.d. copies of D_n with its environment (see fig. 2). To each copy of D_n we associate its renormalized partition function; therefore, to each edge e of D_{m-n} corresponds an independent copy of W_n, $W_n^{(e)}$. By percolation (see fig. 3), we will have, with a positive probability not depending on n, a path in D_{m-n} linking A to B, going only through edges which associated $W_n^{(e)}$ is larger than 1/2.

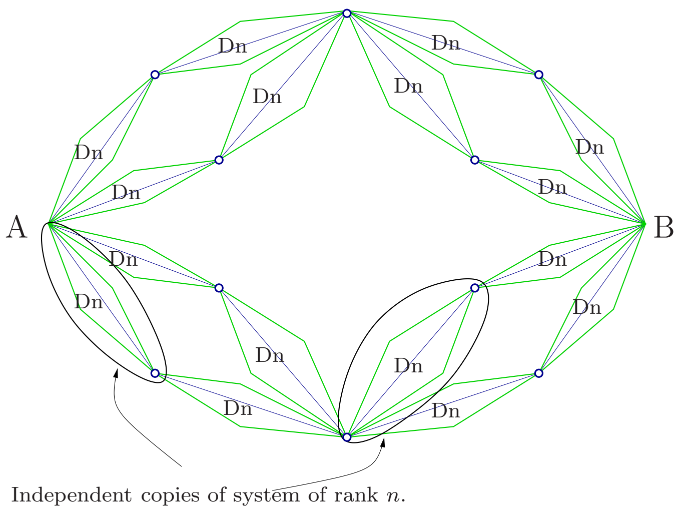

FIGURE 2. On this figure, we scheme how D_{n+m} with its random environment can be seen as independent copies of D_n arrayed as D_m. Here, we have $b = s = 2$ $m = 2$, each diamond corresponds to a copy of D_n (we can identify it with an edge and get the underlying graph D_2). Note that we also have to take into account the environment present on the vertices denoted by circles.

When such paths exist, let γ_0 be one of them (chosen in a deterministic manner, e.g. the lowest such path for some geometric representation of D_n). We look at the

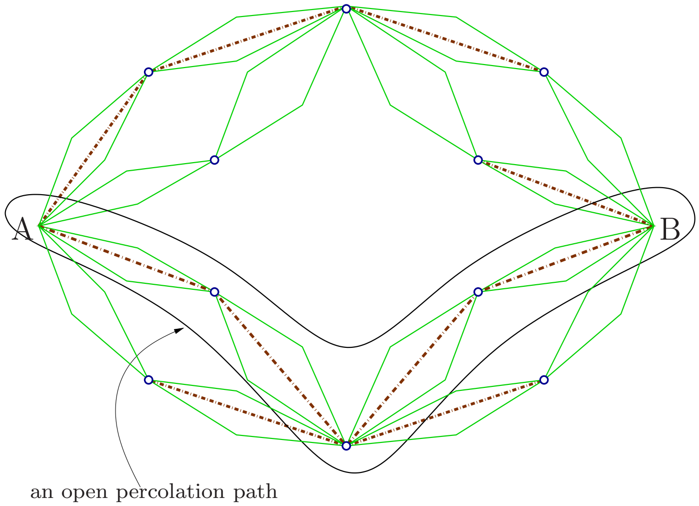

Figure 3. We represent here the percolation argument we use. In the previous figure, we have replaced by an open edge any of the copies of D_n for which satisfies $W_n \geqslant 1/2$. As it happens with probability larger than p_c, it is likely that we can find an open path linking A to B in D_{n+m}, especially if m is large.

contribution of these family of paths in D_m to the partition function. We have

$$W_m \geqslant (1/2)^{s^{m-n}} \exp\left(\sum_{z\in\gamma_0} \beta\omega_z - \lambda(\beta)\right)$$

Again, with positive probability (say larger than 1/3), we have $\sum_{z\in\gamma_0} \omega_z \geqslant 0$ (this can be achieved the the central limit theorem). Therefore with positive probability we have

$$\frac{1}{s^m} \log W_m \geqslant \; -\frac{1}{s^n}(\log 2 + \lambda(\beta)).$$

As $1/s^m \log W_m$ converges in probability to the free energy this proves the result.

□

Proof of the right-inequality in Theorems 2.10 and 2.11. .
The results now follow by combining Lemma 4.1 or 4.2 for β small enough, with Proposition 4.3.

□

5. Fractional moment method, upper bounds and strong disorder

In this section we develop a way to find an upper bound for $\lambda(\beta) - p(\beta)$, or just to find out if strong disorder hold. The main tool we use are fractional moment estimates and measure changes.

5.1. **Fractional moment estimate.** In the sequel we will use the following notation. Given a fixed parameter $\theta \in (0,1)$, define

$$\begin{aligned} u_n &:= QW_n^{\theta}, && (5.1)\\ a_\theta &:= QA^{\theta} = \exp(\lambda(\theta\beta) - \theta\lambda(\beta)). && (5.2) \end{aligned}$$

Proposition 5.1. *The sequence* $(f_n)_n$ *defined by*

$$f_n := \theta^{-1} s^{-n} \log\left(a_\theta b^{\frac{1-\theta}{s-1}} u_n\right)$$

is decreasing and we have

$$\lim_{n\to\infty} f_n \geqslant p(\beta) - \lambda(\beta).$$

(i) In particular, if for some $n \in \mathbb{N}$, $u_n < a_\theta^{-1} b^{\frac{\theta-1}{s-1}}$, *strong disorder holds.*

(ii) Strong disorder holds in particular if $a_\theta < b^{\frac{\theta-1}{s-1}}$.

Proof. The inequality $\left(\sum a_i\right)^\theta \leqslant \sum a_i^\theta$ (which holds for any $\theta \in (0,1)$ and any collection of positive numbers a_i) applied to (1.8) and averaging with respect to Q gives

$$u_{n+1} \leqslant b^{1-\theta} u_n^s a_\theta^{s-1}$$

From this we deduce that the sequence

$$s^{-n} \log\left(a_\theta b^{\frac{1-\theta}{s-1}} u_n\right)$$

is decreasing. Moreover we have

$$p(\beta) - \lambda(\beta) = \lim_{n\to\infty} \frac{1}{s^n} Q \log W_n \leqslant \lim_{n\to\infty} \frac{1}{\theta s^n} \log QW_n^\theta = \lim_{n\to\infty} f_n.$$

As a consequence very strong disorder holds if $f_n < 0$ for any f_n. As a consequence, strong disorder and very strong disorder are equivalent. □

5.2. **Change of measure and environment tilting.** The result of the previous section assures that we can estimate the free energy if we can bound accurately some non integer moment of W_n. Now we present a method to estimate non-integer moment via measure change, it has been introduced to show disorder relevance in the case of wetting on non hierarchical lattice [23] and used since in several different contexts since, in particular for directed polymer models on $\mathbb{Z}^d$, [36]. Yet, for the directed polymer on hierarchical lattice, the method is remarkably simple to apply, and it seems to be the ideal context to present it.

Let $\widetilde{Q}$ be any probability measure such that Q and $\widetilde{Q}$ are mutually absolutely continuous. Using Hölder inequality we observe that

$$QW_n^\theta = \widetilde{Q} \frac{\mathrm{d}Q}{\mathrm{d}\widetilde{Q}} W_n^\theta \leqslant \left[\widetilde{Q}\left(\frac{\mathrm{d}Q}{\mathrm{d}\widetilde{Q}}\right)^{\frac{1}{1-\theta}}\right]^{(1-\theta)} \left(\widetilde{Q} W_n\right)^\theta. \tag{5.3}$$

Our aim is to find a measure $\widetilde{Q}$ such that the term $\left[\widetilde{Q}\left(\frac{\mathrm{d}Q}{\mathrm{d}\widetilde{Q}}\right)^{\frac{1}{1-\theta}}\right]^{(1-\theta)}$ is not very large (i.e. of order 1), and which significantly lowers the expected value of W_n. To do so we look for $\widetilde{Q}$ which lowers the value of the environment on each site, by exponential tilting. For $b<s$ it sufficient to lower the value for the environment uniformly of every site of $D_n\setminus\{A,B\}$ to get a satisfactory result, whereas for the $b=s$ case, on has to do an inhomogeneous change of measure. We present the change of measure in a united framework before going to the details with two separate cases.

Recall that V_i denotes the sites of $D_i\setminus D_{i+1}$, and that the number of sites in D_n is

$$|D_n\setminus\{A,B\}|=\sum_{i=1}^n|V_i|=\sum_{i=1}^n(s-1)b^is^{i-1}=\frac{(s-1)b((sb)^n-1)}{sb-1} \tag{5.4}$$

We define $\widetilde{Q}=\widetilde{Q}_{n,s,b}$ to be the measure under which the environment on the site of the i-th generation for $i\in\{1,\dots,n\}$ are standard gaussians with mean $-\delta_i=\delta_{i,n}$, where $\delta_{i,n}$ is to be defined. The density of $\widetilde{Q}$ with respect to Q is given by

$$\frac{\mathrm{d}\widetilde{Q}}{\mathrm{d}Q}(\omega)=\exp\left(-\sum_{i=1}^n\sum_{z\in V_i}(\delta_{i,n}\omega_z+\frac{\delta_{i,n}^2}{2})\right).$$

As each path in D_n intersects V_i on $s^{i-1}(s-1)$ sites, this change of measure lowers the value of the Hamiltonian (1.1) by $\sum_{i=1}^n s^{i-1}(s-1)\delta_{i,n}$ on any path. Therefore, both terms can be easily computed,

$$\widetilde{Q}\left(\frac{\mathrm{d}Q}{\mathrm{d}\widetilde{Q}}\right)^{\frac{1}{1-\theta}}=\exp\left\{\frac{\theta}{2(1-\theta)}\sum_{i=1}^n|V_i|\delta_{i,n}^2\right\}. \tag{5.5}$$

$$\left(\widetilde{Q}W_n\right)^{\theta}=\exp\left\{-\beta\theta\sum_{i=1}^n s^{i-1}(s-1)\delta_{i,n}\right\}. \tag{5.6}$$

Replacing (5.6) and (5.5) back into (5.3) gives

$$u_n\leqslant\exp\left\{\theta\sum_{i=1}^n\left(\frac{|V_i|\delta_{i,n}^2}{2(1-\theta)}-\beta s^{i-1}(s-1)\delta_{i,n}\right)\right\}. \tag{5.7}$$

When $\delta_{i,n}=\delta_n$ (i.e. when the change of measure is homogeneous on every site) the last expression becomes simply

$$u_n\leqslant\exp\left\{\theta\left(\frac{|D_n\setminus\{A,B\}|\delta_n^2}{2(1-\theta)}-(s^n-1)\beta\delta_n\right)\right\}. \tag{5.8}$$

In either case, the rest of the proof then consists in finding convenient values for $\delta_{i,n}$ and n large enough to insure that (i) from Proposition 5.1 holds.

5.3. **Homogeneous shift method:** $s > b$.

Proof of the left inequality in Theorem 2.10, in the gaussian case. Let $0 < \theta < 1$ be fixed (say $\theta = 1/2$) and $\delta_{i,n} = \delta_n := (sb)^{-n/2}$.
Observe from (5.4) that $|D_n \setminus \{A, B\}|\delta_n^2 \leqslant 1$, so that (5.8) implies

$$u_n \leqslant \exp\left(\frac{\theta}{2(1-\theta)} - \theta\beta(s/b)^{n/2}\frac{s-1}{s}\right).$$

Taking $n = \frac{2(|\log\beta|+\log c_3)}{\log s - \log b}$, we get

$$u_n \leqslant \exp\left(\frac{\theta}{2(1-\theta)} - \frac{\theta c_5 s}{s-1}\right).$$

Choosing $\theta = 1/2$ and c_3 sufficiently large, we have

$$f_n = s^{-n}\log a_\theta b^{\frac{1-\theta}{s-1}} u_n \leqslant -s^{-n}, \tag{5.9}$$

so that Proposition 5.1 gives us the conclusion

$$p(\beta) - \lambda(\beta) \leqslant -s^{-n} = -(\beta/c_3)^{\frac{2\log s}{\log s - \log b}}.$$

□

5.4. **Inhomogeneous shift method:** $s = b$.

One can check that the previous method does not give good enough results for the marginal case $b = s$. One has to do a change of measure which is a bit more refined and for which the intensity of the tilt in proportional to the Green Function on each site. This idea was used first for the marginal case in pinning model on hierarchical lattice (see [35]).

Proof of the left inequality in Theorem 2.11, the gaussian case. This time, we set $\delta_{i,n} := n^{-1/2}s^{-i}$. Then (recall (5.4)), (5.7) becomes

$$u_n \leqslant \exp\left(\frac{\theta}{2(1-\theta)}\frac{s-1}{s} - \theta\beta n^{-1/2}\frac{s-1}{s}\right).$$

Taking $\theta = 1/2$ and $n = (c_4/\beta)^2$ for a large enough constant c_4, we get that $f_n \leqslant -s^n$ and applying Proposition 5.1, we obtain

$$p(\beta) - \lambda(\beta) \leqslant -s^{-n} = -s^{-(c_4/\beta)^2} = \exp\left(-\frac{c_4^2\log s}{\beta^2}\right).$$

□

5.5. **Bounds for the critical temperature.** From Proposition 5.1, we have that strong disorder holds if $a_\theta < b^{(1-\theta)/(s-1)}$. Taking logarithms, this condition reads

$$\lambda(\theta\beta) - \theta\lambda(\beta) < (1-\theta)\frac{\log b}{s-1}.$$

We now divide both sides by $1-\theta$ and let $\theta \to 1$. This proves part (*iii*) of Proposition 2.7.

For the case $b > s$, this condition can be improved by the inhomogeneous shifting method; here, we perform it just in the gaussian case. Recall that

$$u_n \leqslant \exp\left\{\theta \sum_{i=1}^{n} \left(\frac{|V_i|\delta_{i,n}^2}{2(1-\theta)} - \beta s^{i-1}(s-1)\delta_{i,n}\right)\right\}. \tag{5.10}$$

We optimize each summand in this expression taking $\delta_{i,n} = \delta_i = (1-\theta)\beta/b^i$. Recalling that $|V_i| = (bs)^{i-1}b(s-1)$, this yields

$$\begin{aligned} u_n &\leqslant \exp\left\{-\theta(1-\theta)\frac{\beta^2}{2}\frac{s-1}{s}\sum_{i=1}^{n}\left(\frac{s}{b}\right)^i\right\} \\ &\leqslant \exp\left\{-\theta(1-\theta)\frac{\beta^2}{2}\frac{s-1}{s}\frac{s/b-(s/b)^{n+1}}{1-s/b}\right\}. \end{aligned}$$

Because n is arbitrary, in order to guaranty strong disorder it is enough to have (cf. first condition in Proposition 5.1) for some $\theta \in (0,1)$

$$\theta(1-\theta)\frac{\beta^2}{2}\frac{s-1}{s}\frac{s/b}{1-s/b} > (1-\theta)\frac{\log b}{s-1} + \log a_\theta.$$

In the case of gaussian variables $\log a_\theta = \theta(\theta-1)\beta^2/2$. This is equivalent to

$$\frac{\beta^2}{2} > \frac{(b-s)\log b}{(b-1)(s-1)}.$$

This last condition is an improvement of the bound in part (*iii*) of Proposition 2.7.

5.6. **Adaptation of the proofs for non-gaussian variables.**

Proof of the left inequality in Theorem 2.10 and 2.11, the general case. To adapt the preceding proofs to non-gaussian variables, we have to investigate the consequence of exponential tilting on non-gaussian variables. We sketch the proof in the inhomogeneous case $b = s$, we keep $\delta_{i,n} := s^{-i}n^{-1/2}$.

Consider $\widetilde{Q}$ with density

$$\frac{\mathrm{d}\widetilde{Q}}{\mathrm{d}Q}(\omega) := \exp\left(-\sum_{i=1}^{n}\sum_{z\in V_i}\left(\delta_{i,n}\omega_z + \lambda(-\delta_{i,n})\right)\right),$$

(recall that $\lambda(x) := \log Q \exp(x\omega)$). The term giving cost of the change of measure is, in this case,

$$\begin{aligned}\left[\widetilde{Q}\left(\frac{\mathrm{d}Q}{\mathrm{d}\widetilde{Q}}\right)^{\frac{1}{1-\theta}}\right]^{(1-\theta)} &= \exp\left((1-\theta)\sum_{i=1}^{n}|V_i|\left[\lambda\left(\frac{\theta\delta_{i,n}}{1-\theta}\right)+\frac{\theta}{1-\theta}\lambda(-\delta_{i,n})\right]\right)\\ &\leqslant \exp\left(\frac{\theta}{(1-\theta)}\sum_{i=1}^{n}|V_i|\delta_{i,n}^2\right) \leqslant \exp\left(\frac{\theta}{(1-\theta)}\right)\end{aligned}$$

Where the inequality is obtained by using the fact the $\lambda(x) \sim_0 x^2/2$ (this is a consequence of the fact that ω has unit variance) so that if β is small enough, one can bound every $\lambda(x)$ in the formula by x^2.

We must be careful when we estimate $\widetilde{Q}W_n$. We have

$$\widetilde{Q}W_n = \exp\left(\sum_{i=1}^{n}(s-1)s^{i-1}\lambda(\beta-\delta_{i,n})-\lambda(\beta)-\lambda(-\delta_{i,n})\right)QW_n$$

By the mean value theorem

$$\lambda(\beta-\delta_{i,n})-\lambda(\beta)-\lambda(-\delta_{i,n})+\lambda(0) = -\delta_{i,n}\left(\lambda'(\beta-t_0)-\lambda'(-t_0)\right) = -\delta_{i,n}\beta\lambda''(t_1),$$

for some $t_0 \in (0,\delta_{i,n})$ and some $t_1 \in (\beta,-\delta_{i,n})$. As we know that $\lim_{\beta\to 0}\lambda''(\beta) = 1$, when δ_i and β are small enough, the right-hand side is less than $-\beta\delta_{i,n}/2$. Hence,

$$\widetilde{Q}W_n \leqslant \exp\left(\sum_{i=1}^{n}(s-1)s^{i-1}\frac{\beta\delta_{i,n}}{2}\right).$$

We get the same inequalities that in the case of gaussian environment, with different constants, which do not affect the proof. The case $b < s$ is similar. □

6. Fluctuation and localisation results

In this section we use the shift method we have developed earlier to prove fluctuation results

6.1. **Proof of Proposition 2.12.** The statement on the variance is only a consequence of the second statement. Recall that the random variable ω_z here are i.i.d. centered standard gaussians, and that the product law is denoted by Q. We have to prove

$$Q\left\{\log Z_n \in [a, a+\beta\varepsilon(s/b)^{n/2}]\right\} \leqslant 4\varepsilon \quad \forall\varepsilon > 0, n \geqslant 0, a \in \mathbb{R} \tag{6.1}$$

Assume there exist real numbers a and ε, and an integer n such that (6.1) does not hold, i.e.

$$Q\left\{\log \bar{Z}_n \in [a, a+\beta\varepsilon(s/b)^{n/2})\right\} > 4\varepsilon. \tag{6.2}$$

Then one of the following holds

$$\begin{aligned} &Q\left\{\log Z_n \in [a, a+\beta\varepsilon(s/b)^{n/2})\right\} \cap \left\{\sum_{z\in D_n} \omega_z \geqslant 0\right\} > 2\varepsilon, \\ &Q\left\{\log Z_n \in [a, a+\beta\varepsilon(s/b)^{n/2})\right\} \cap \left\{\sum_{z\in D_n} \omega_z \leqslant 0\right\} > 2\varepsilon. \end{aligned} \tag{6.3}$$

We assume that the first line is true. We consider the events related to Q as sets of environments $(\omega_z)_{z\in D_n\setminus\{A,B\}}$. We define

$$A_\varepsilon = \left\{\log Z_n \in [a, a+\beta\varepsilon b^{-n/2})\right\} \cap \left\{\sum_{z\in D_n} \omega_z \geqslant 0\right\}, \tag{6.4}$$

and

$$A_\varepsilon^{(i)} = Q\left\{\log Z_n \in [a - i\beta\varepsilon(s/b)^{n/2}, a-(i-1)\beta\varepsilon(s/b)^{n/2})\right\}. \tag{6.5}$$

Define $\delta = \frac{s^{n/2}}{(s^n-1)b^{n/2}}$. We define the measure $\widetilde{Q}_{i,\varepsilon}$ with its density:

$$\frac{\mathrm{d}\widetilde{Q}_{i,\varepsilon}}{\mathrm{d}Q}(\omega) := \exp\left(\left[i\varepsilon\delta^2 \sum_{z\in D_n} \omega_z\right] - \frac{i^2\varepsilon^2\delta^2|D_n\setminus\{A,B\}|}{2}\right). \tag{6.6}$$

If the environment $(\omega_z)_{z\in D_n}$ has law Q then $(\widehat{\omega}_z^{(i)})_{z\in D_n}$ defined by

$$\widehat{\omega}_z^{(i)} := \omega_z + \varepsilon i\delta, \tag{6.7}$$

has law $\widetilde{Q}_{i,\varepsilon}$. Going from ω to $\widehat{\omega}^{(i)}$, one increases the value of the Hamiltonian by $\varepsilon i(s/b)^{n/2}$ (each path cross s^n-1 sites). Therefore if $(\widehat{\omega}_z^{(i)})_{z\in D_n} \in A_\varepsilon$, then $(\omega_z)_{z\in D_n} \in A_\varepsilon^{(i)}$. From this we have $\widetilde{Q}_{i,\varepsilon}A_\varepsilon \leqslant QA_\varepsilon^{(i)}$, and therefore

$$QA_\varepsilon^{(i)} \geqslant \int_{A_\varepsilon} \frac{\mathrm{d}\widetilde{Q}_{i,\varepsilon}}{\mathrm{d}Q} Q(\,\mathrm{d}\omega) \geqslant \exp(-(\varepsilon i)^2/2)Q(A_\varepsilon). \tag{6.8}$$

The last inequality is due to the fact that the density is always larger than $\exp(-(\varepsilon i)^2/2)$ on the set A_ε (recall its definition and the fact that $|D_n\setminus\{A,B\}|\delta^2 \leqslant 1$). Therefore, in our setup, we have

$$QA_\varepsilon^{(i)} > \varepsilon, \quad \forall i \in [0, \varepsilon^{-1}]. \tag{6.9}$$

As the $A_\varepsilon^{(i)}$ are disjoints, this is impossible. If we are in the second case of (6.3), we get the same result by shifting the variables in the other direction. □

6.2. **Proof of Proposition 2.13.** Let us suppose that there exist n, ε and a such that

$$Q\left\{\log Z_n \in [a, a+\beta\varepsilon\sqrt{n})\right\} > 8\varepsilon. \tag{6.10}$$

We define $\delta_{i,n} = \delta_i := \varepsilon s^{1-i}(s-1)^{-1}n^{-1/2}$. Then one of the following inequality holds (recall the definition of V_i)

$$\begin{aligned}
&Q\left\{\log Z_n \in [a, a+\beta\varepsilon\sqrt{n})\right\} \cap \left\{\sum_{i=1}^{n} \delta_i \sum_{z\in V_i} \omega_z \geqslant 0\right\} > 4\varepsilon,\\
&Q\left\{\log Z_n \in [a, a+\beta\varepsilon\sqrt{n})\right\} \cap \left\{\sum_{i=1}^{n} \delta_i \sum_{z\in V_i} \omega_z \leqslant 0\right\} > 4\varepsilon.
\end{aligned} \tag{6.11}$$

We assume that the first line holds and define

$$A_\varepsilon = \left\{\log Z_n \in [a, a+\beta\varepsilon\sqrt{n})\right\} \cap \left\{\sum_{i=1}^{n} \delta_i \sum_{z\in V_i} \omega_z \geqslant 0\right\} \tag{6.12}$$

And

$$A_\varepsilon^{(j)} = \left\{\log Z_n \in [a - j\beta\varepsilon\sqrt{n}, a-(j-1)\beta\varepsilon\sqrt{n})\right\} \tag{6.13}$$

$$j\beta \sum_{i=1}^{n} \delta_i (s-1)s^{i-1} = j\beta\varepsilon\sqrt{n}. \tag{6.14}$$

Therefore, an environment $\omega \in A_\varepsilon$ will be transformed in an environment in $A_\varepsilon^{(j)}$.

We define $\widetilde{Q}_{j,\varepsilon}$ the measure whose Radon-Nicodyn derivative with respect to Q is

$$\frac{\mathrm{d}\widetilde{Q}_{i,\varepsilon}}{\mathrm{d}Q}(\omega) := \exp\left(\left[j\sum_{i=1}^{n} \delta_i \sum_{z\in V_i} \omega_z\right] - \sum_{i=1}^{n} \frac{j^2\delta_i^2|V_i|}{2}\right). \tag{6.15}$$

We can bound the deterministic term.

$$\sum_{i=1}^{n} \frac{j^2\delta_i^2|V_i|}{2} = j^2\varepsilon^2 \sum_{i=1}^{n} \frac{s}{2(s-1)} \leqslant j^2\varepsilon^2. \tag{6.16}$$

For an environment $(\omega_z)_{z\in D_n\setminus\{A,B\}}$, define $(\widehat{\omega}_z^{(j)})_{z\in D_n\setminus\{A,B\}}$ by

$$\widehat{\omega}_z^{(j)} := \omega_z + j\varepsilon\delta_i, \quad \forall z \in V_i. \tag{6.17}$$

If $(\omega_z)_{z\in D_n\setminus\{A,B\}}$ has Q, then $(\widehat{\omega}_z^{(j)})_{z\in D_n\setminus\{A,B\}}$ has law $\widetilde{Q}_{j,\varepsilon}$. When one goes from ω to $\widehat{\omega}^{(j)}$, the value of the Hamiltonian is increased by

$$\sum_{i=1}^{n} j\delta_i s^{i-1}(s-1) = \varepsilon\sqrt{n}.$$

Therefore, if $\widehat{\omega}^{(j)} \in A_\varepsilon$, then $\omega \in A_\varepsilon^{(j)}$, so that

$$QA_\varepsilon^{(j)} \geqslant \widetilde{Q}_{j,\varepsilon}A_\varepsilon.$$

Because of the preceding remarks

$$QA_\varepsilon^{(j)} \geqslant \widetilde{Q}_{j,\varepsilon}A_\varepsilon = \int_{A_\varepsilon} \frac{\mathrm{d}\widetilde{Q}_{i,\varepsilon}}{\mathrm{d}Q} Q(\mathrm{d}\omega) \geqslant \exp\left(-j^2\varepsilon^2\right) QA_\varepsilon. \tag{6.18}$$

The last inequality comes from the definition of A_ε which gives an easy lower bound on the Radon-Nicodyn derivative. For $j \in [0, (\varepsilon/2)^{-1}]$, this implies that $QA_\varepsilon^{(j)} > 2\varepsilon$.

As they are disjoint events this is impossible. The second case of (6.11) can be dealt analogously. □

6.3. **Proof of Corollary 2.14.** Let $g \in \Gamma_n$ be a fixed path. For $m \geqslant n$, define

$$Z_m^{(g)} := \sum_{\{g' \in \Gamma_m : g|_n = g\}} \exp\left(\beta H_m(g')\right). \tag{6.19}$$

With this definition we have

$$\mu_m(\gamma|_n = g) = \frac{Z_m^{(g)}}{Z_m}. \tag{6.20}$$

To show our result, it is sufficient to show that for any constant K and any distinct $g, g' \in \Gamma_n$

$$\lim_{m\to\infty} Q\left(\frac{\mu_m(\gamma|_n = g)}{\mu_m(\gamma|_n = g')} \in [K^{-1}, K]\right) = 0. \tag{6.21}$$

For g and g' distinct, it is not hard to see that

$$\log\left(\frac{\mu_m(\gamma|_n = g)}{\mu_m(\gamma|_n = g')}\right) = \log Z_m^{(g)} - \log Z_m^{(g')} =: \log Z_{m-n}^{(0)} + X, \tag{6.22}$$

where $Z_{m-n}^{(0)}$ is a random variable whose distribution is the same as the one of Z_{m-n}, and X is independent of $Z_{m-n}^{(0)}$. We have

$$\begin{aligned} Q&\left(\log\left(\frac{\mu_m(\gamma|_n = g)}{\mu_m(\gamma|_n = g')}\right) \in [-\log K, \log K]\right) \\ &= Q\left[Q\left(\log Z_{m-n}^{(0)} \in [-\log K - X, \log K - X] \,\middle|\, X\right)\right] \\ &\leqslant \max_{a\in\mathbb{R}} Q\left(\log Z_{m-n} \in [a, a + 2\log K]\right). \end{aligned} \tag{6.23}$$

Proposition 2.12 and 2.13 show that the right–hand side tends to zero. □

7. The weak disorder polymer measure

Comets and Yoshida introduced in [15] an infinite volume Markov chain at weak disorder that corresponds in some sense to the limit of the polymers measures μ_n when n goes to infinity. We perform the same construction here. The notation is more cumbersome in our setting.

Recall that Γ_n is the space of directed paths from A to B in D_n. Denote by P_n the uniform law on Γ_n. For $g \in \Gamma_n$, $0 \leqslant t \leqslant s^n - 1$, define $W_\infty(g_t, g_{t+1})$ by performing the same construction that leads to W_∞, but taking g_t and g_{t+1} instead of A and B respectively. On the classical directed polymers on $\mathbb{Z}^d$, this would be equivalent to take the (t, g_t) as the initial point of the polymer.

We can now define the weak disorder polymer measure for $\beta < \beta_0$. We define Γ as the projective limit of Γ_n (with its natural topology), the set of path on $D := \bigcup_{n\geqslant 1} D_n$. As for finite path, we can define, for $\bar{g} \in \Gamma$, its projection onto Γ_n, $\bar{g}|_n$. We define

$$\mu_\infty(\bar\gamma|_n = g) := \frac{1}{W_\infty}\exp\{\beta H_n(g) - (s^n-1)\lambda(\beta)\}\prod_{i=0}^{s^n-1} W_\infty(g_i, g_{i+1})\, P_n(\bar\gamma|_n = g)(7.1)$$

Let us stress the following:

- Note that the projection on the different Γ_n are consistent (so that our definition makes sense)

  $$\mu_\infty(\bar\gamma|_n = g) = \mu_\infty\left((\bar\gamma|_{n+1})|_n = g\right).$$

- Thanks to the martingale convergence for both the numerator and the denominator, for any $\mathbf{s} \in \Gamma_n$,

  $$\lim_{k\to+\infty} \mu_{k+n}(\gamma|_n = g) = \mu_\infty(\bar\gamma|_n = g).$$

  Therefore, μ_∞ is the only reasonable definition for the limit of μ_n.

It is an easy task to prove the law of large numbers for the time-averaged quenches mean of the energy. This follows as a simple consequence of the convexity of $p(\beta)$.

Proposition 7.1. *At each point where p admits a derivative,*

$$\lim_{n\to+\infty} \frac{1}{s^n}\mu_n(H_n(\gamma)) \to p'(\beta), \quad Q-a.s..$$

Proof. It is enough to observe that

$$\frac{d}{d\beta}\log Z_n = \mu_n(H_n(\gamma)),$$

then use the convexity to pass to the limit. □

We can also prove a quenched law of large numbers under our infinite volume measure μ_∞, for almost every environment. The proof is very easy, as it involves just a second moment computation.

Proposition 7.2. *At weak disorder,*

$$\lim_{n\to+\infty} \frac{1}{s^n} H_n(\bar\gamma|_n) = \lambda'(\beta), \quad \mu_\infty - a.s., Q-a.s..$$

Proof. We will consider the following auxiliary measure (size biased measure) on the environment

$$\overline{Q}(f(\omega)) = Q(f(\omega)W_{+\infty}).$$

So, Q-a.s. convergence will follow from $\overline{Q}$-a.s. convergence. This will be done by a direct computation of second moments. Let us write $\Delta = Q(\omega^2 e^{\beta\omega - \lambda(\beta)})$.

$$\begin{aligned}
&\overline{Q}\left(\mu_\infty(|H_n(\bar\gamma|_n)|^2)\right)\\
= \;& Q\left[P_n\left(|H_n(\gamma)|^2\exp\{\beta H_n(\gamma)-(s^n-1)\lambda(\beta)\}\prod_{i=0}^{s^n-1}W_\infty(\gamma_i,\gamma_{i+1})\right)\right]\\
= \;& Q\left[P_n(|H_n(\gamma)|^2\exp\{\beta H_n(\gamma)-(s^n-1)\lambda(\beta)\})\right]\\
= \;& Q\left[P_n(|\sum_{t=1}^{s^n}\omega(\gamma_t)|^2\exp\{\beta H_n(\gamma)-(s^n-1)\lambda(\beta)\})\right]\\
= \;& Q\left[\sum_{t=1}^{s^n-1}P_n\left(|\omega(\gamma_t)|^2\exp\{\beta H_n(\gamma)-(s^n-1)\lambda(\beta)\}\right)\right]\\
& +Q\left[\sum_{1\,\leqslant\, t_1\neq t_2\,\leqslant\, s^n-1}P_n\left(\omega(\gamma_{t_1})\omega(\gamma_{t_2})\exp\{\beta H_n(\gamma)-(s^n-1)\lambda(\beta)\}\right)\right]\\
= \;& (s^n-1)\Delta+(s^n-1)(s^n-2)(\lambda'(\beta))^2,
\end{aligned}$$

where we used independence to pass from line two to line three. So, recalling that $\overline{Q}(\mu_\infty(H_n(\bar\gamma_n))=(s^n-1)\lambda'(\beta)$, we have

$$\begin{aligned}
&\overline{Q}\left(\mu_\infty(|H_n(\gamma^{(n)})-(s^n-1)\lambda'(\beta)|^2)\right)\\
= \;& (s^n-1)\Delta+(s^n-1)(s^n-2)(\lambda'(\beta))^2-2(s^n-1)\lambda'(\beta)\overline{Q}\left(\mu_\infty(H_n(\bar\gamma_n))\right)\\
&+(s^n-1)^2(\lambda'(\beta))^2\\
= \;& (s^n-1)\left(\Delta-(\lambda'(\beta)^2)\right).
\end{aligned}$$

Then

$$\overline{Q}\mu_\infty\left(\left|\frac{H_n(\bar\gamma_n)-(s^n-1)\lambda'(\beta)}{s^n}\right|^2\right)\leqslant\frac{1}{s^n}\left(\Delta-(\lambda'(\beta)^2)\right),$$

so the result follows by Borel-Cantelli. □

8. Some remarks on the bond–disorder model

In this section, we shortly discuss, without going through the details, how the methods we used in this paper could be used (or could not be used) for the model of directed polymer on the same lattice with disorder located on the bonds.

In this model to each bond e of D_n we associate i.i.d. random variables ω_e. We consider each set $g\in\Gamma_n$ as a set of bonds and define the Hamiltonian as

$$H_n^\omega(g)=\sum_{e\in g}\omega_e, \tag{8.1}$$

The partition function Z_n is defined as

$$Z_n := \sum_{g \in \Gamma_n} \exp(\beta H_n(g)). \tag{8.2}$$

One can check that is satisfies the following recursion

$$\begin{aligned} Z_0 &\overset{\mathcal{L}}{=} \exp(\beta\omega) \\ Z_{n+1} &\overset{\mathcal{L})}{=} \sum_{i=1}^{b} Z_n^{(i,1)} Z_n^{(i,2)} \dots Z_n^{(i,s)}. \end{aligned} \tag{8.3}$$

where equalities hold in distribution and and $Z_n^{i,j}$ are i.i.d. distributed copies of Z_n. Because of the loss of the martingale structure and the homogeneity of the Green function in this model (which is equal to b^{-n} on each edge), Lemma 2.4 does not hold, and we cannot prove part (iv) in Proposition 2.7, Theorem 2.11 and Proposition 2.13 for this model. Moreover we have to change $b \leqslant s$ by $b < s$ in (v) of Proposition 2.7. Moreover, the method of the control of the variance would give us a result similar to 2.11 in this case

Proposition 8.1. *When b is equal to s, on can find constants c and β_0 such that for all $\beta \leqslant \beta_0$*

$$0 \leqslant \lambda(\beta) - p(\beta) \leqslant \exp\left(-\frac{c}{\beta^2}\right). \tag{8.4}$$

However, we would not be able to prove that annealed and free energy differs at high temperature for $s = b$ using our method. The techniques used in [24] or [36] for dimension 2 should be able to tackle this problem, and show marginal disorder relevance in this case as well.

Acknowledgements: The authors are very grateful to Francis Comets and Giambattista Giacomin for their suggestion to work on this subject and many enlightning discussions.
